Application of the 2013 Heart Failure (HF) Treatment Guidelines

For Nurses
Disclosures

Faculty Disclosure
As a sponsor accredited by the ACCME, the ACPE and the ANCC to provide continuing education for the healthcare team, OptumHealth Education requires the disclosure of all relevant financial relationships a faculty member has with any commercial interest. The faculty reported the following:

• Ms. Snell is an employee of BioScrip.

Reviewer Disclosures
To ensure fair balance and avoid bias, the content for this activity has been reviewed by an independent medical expert with no relevant financial relationships and has been approved by OptumHealth Education.
U.S Heart Failure Epidemiology

• Heart Failure (HF) has reached epidemic levels, especially for the elderly

• Around 5.1 million Americans have HF (2013)
• Approximately 670,000 new HF cases each year (2013)
• In 2010, HF underlying cause of 57,757 deaths
• HF costs an estimated $32 billion (2011)

http://www.cdc.gov/dhdsp/data_statistics/fact_sheets/fs_heart_failure.htm; Accessed May 12, 2014
Total number of deaths due to cardiovascular diseases in the world: 17 327 000

Europe
4 584 000

East Med.
1 195 000

Western Pacific
4 735 000

The Americas

U.S Heart Failure Demographics
Heart Failure Hospitalizations

• Medicare heart failure readmissions = 24% within 30 days\(^1\)
• Mean age of hospitalized patients 70-75 yrs\(^2\)
• 50% female (larger proportion in US)\(^2\)
• 20% African American; 7% Hispanic\(^2\)
• Etiology of HF\(^2\)
  • Ischemic
  • Uncontrolled hypertension, congenital, valvular pathology in developing nations

U.S Heart Failure Demographics
Heart Failure Hospitalizations

• Comorbidities
  • Cardiac
    • Coronary artery disease
    • Myocardial infarction 20-30%
    • Hypertension
    • AF
  • Non-cardiac
    • Diabetes
    • Chronic kidney disease
    • COPD

• Mean length of stay: 4-20 days
• In-hospital mortality 4-30%

Objectives

Participants will be able to:

- Describe the clinical presentation and diagnosis of heart failure
- Apply the 2013 ACCF/AHA treatment guidelines throughout all stages of heart failure
Normal Heart Function

Aorta (to body)
Pulmonary artery
Left pulmonary arteries (to left lung)
Left pulmonary veins (from left lung)
Left atrium
Mitral valve
Left ventricle

Superior vena cava (from upper body)
Right pulmonary arteries (to right lung)
Aortic valve
Right pulmonary veins (from right lung)
Right atrium
Tricuspid valve
Inferior vena cava (from lower body)

Pulmonary valve
Direction of blood flow
Right ventricle
Septum

National Heart, Lung & Blood Institute, US Dept. Health & Human Services, National Institutes of Health
Heart Failure Pathophysiology

- Myocardial Injury
  - Hemodynamic Abnormalities
  - Symptomatology
- Neuroendocrine Activation
  - Cardiac Remodeling
  - Disease Progression
  - Mortality

Adapted from Greenberg and Barnard (2005)
Remodeling of the Heart

The heart undergoes continual remodeling in response to fluctuations in functional demand (cardiac remodeling). Pathological hemodynamic overloading (e.g. hypertension and myocardial infarction) and unloading (e.g. prolonged bed rest and ventricular assist device) induce pathological hypertrophy and atrophy respectively.

Atrophy
- Hemodynamic unloading
  - Decrease myocardial mass
  - Protein synthesis < degradation
  - Fetal metabolic shift
  - Fetal myocardial gene expression

Normal Heart
- Hemodynamic unloading

Pathological hypertrophy
- Hemodynamic overloading
  - Increase myocardial mass
  - Protein synthesis > degradation
  - Fetal metabolic shift
  - Fetal myocardial gene expression

2013 ACCF/AHA HEART FAILURE GUIDELINES

The full-text guidelines are also available on the following Web sites:
ACC (www.cardiosource.org) and AHA (my.americanheart.org)
Heart Failure Defined

- Heart Failure (HF) - ICD-9 428; ICD-10 I50
- The chronic inability of the heart to supply sufficient blood flow to meet the body's needs. Manifests as either:
  - A “pump” problem –
    - The heart can not force the blood out
  - A “relaxation” problem
    - The heart muscle do not relax enough to allow the heart to fill with enough blood to meet the needs of the body
Heart Failure Types

- **Heart failure with reduced ejection fraction (HFrEF)** (systolic/left-sided)
  - Ejection fraction (EF) <40%

- **Heart failure with preserved ejection fraction (HFpEF)** (diastolic/right-sided)
  - Ejection fraction (EF) >40% (normal)

Ejection Fraction 41-49% is borderline and treated as HFpEF
EF in HFrEF

EF = 50%

National Heart, Lung & Blood Institute, US Dept. Health & Human Services,
National Institutes of Health
EF in HFpEF

EF = 50%

National Heart, Lung & Blood Institute, US Dept. Health & Human Services,
National Institutes of Health
Clinical Presentation of HF

- Decreased exercise tolerance/SOB
- Fluid retention
- Jugular venous distension (JVD)
- Need to sleep with more pillows or in recliner
  - Paroxymal nocturnal dyspnea (PND)
- Arrhythmias
- No symptoms or symptoms of HF, but have evidence of cardiac enlargement or dysfunction
Classifications of Heart Failure

• **The New York Heart Association classification**
  • Focuses on functional capacity/symptoms
  • Most widely used in practice

• **The American College of Cardiology/American Heart Association (ACC/AHA) stages**
  • Focuses on the progressive nature of HF
  • Most widely used in literature

</tbody>
</table>
Initial and Serial Evaluation
A thorough history and physical examination should be obtained/ performed in patients presenting with HF to identify cardiac and noncardiac disorders or behaviors that might cause or accelerate the development or progression of HF.

In patients with idiopathic dilated cardiomyopathy, a 3-generational family history should be obtained to aid in establishing the diagnosis of familial DCM.

Volume status and vital signs should be assessed at each patient encounter. This includes serial assessment of weight, as well as estimates of jugular venous pressure and the presence of peripheral edema or orthopnea.
Diagnostic Tests

Initial laboratory evaluation of patients presenting with HF should include:
- Complete blood count
- Urinalysis
- Serum electrolytes (including calcium and magnesium)
- Blood urea nitrogen, serum creatinine
- Glucose
- Fasting lipid profile
- Liver function tests
- Thyroid-stimulating hormone.

Serial monitoring, when indicated, should include serum electrolytes and renal function.
Diagnostic Tests (cont.)

A 12-lead ECG should be performed initially on all patients presenting with HF.

Screening for hemochromatosis or HIV is reasonable in selected patients who present with HF.

Diagnostic tests for rheumatologic diseases, amyloidosis, or pheochromocytoma are reasonable in patients presenting with HF in whom there is a clinical suspicion of these diseases.
In ambulatory patients with dyspnea, measurement of BNP or N-terminal pro-B-type natriuretic peptide (NT-proBNP) is useful to support clinical decision making regarding the diagnosis of HF, especially in the setting of clinical uncertainty.

Measurement of BNP or NT-proBNP is useful for establishing prognosis or disease severity in chronic HF.
Biomarkers: Ambulatory (cont’)

BNP- or NT-proBNP guided HF therapy can be useful to achieve optimal dosing of GDMT in select clinically euvolemic patients followed in a well-structured HF disease management program.

The usefulness of serial measurement of BNP or NT-proBNP to reduce hospitalization or mortality in patients with HF is not well established.

Measurement of other clinically available tests such as biomarkers of myocardial injury or fibrosis may be considered for additive risk stratification in patients with chronic HF.
Biomarkers: Acute Care

Measurement of BNP or NT-proBNP is useful to support clinical judgment for the diagnosis of acutely decompensated HF, especially in the setting of uncertainty for the diagnosis.

Measurement of BNP or NT-proBNP and/or cardiac troponin is useful for establishing prognosis or disease severity in acutely decompensated HF.
Biomarkers: Acute Care (cont’)

The usefulness of BNP- or NT-proBNP guided therapy for acutely decompensated HF is not well-established.

Measurement of other clinically available tests such as biomarkers of myocardial injury or fibrosis may be considered for additive risk stratification in patients with acutely decompensated HF.

Stage A

Control hypertension
Hypertension and lipid disorders should be controlled in accordance with contemporary guidelines to lower the risk of HF.

Reduce contributors/comorbidites
Other conditions that may lead to or contribute to HF, such as obesity, diabetes mellitus, tobacco use, and known cardiotoxic agents, should be controlled or avoided.
TREATMENT OF STAGES A TO D

Stage B
Stage B

Ace inhibitors/Angiotensin Receptor Blockers

In all patients with a recent or remote history of MI or ACS and reduced EF, ACE inhibitors should be used to prevent symptomatic HF and reduce mortality. In patients intolerant of ACE inhibitors, ARBs are appropriate unless contraindicated.

ACE inhibitors should be used in all patients with a reduced EF to prevent symptomatic HF, even if they do not have a history of MI.

Beta blockers

In all patients with a recent or remote history of MI or ACS and reduced EF, evidence-based beta blockers should be used to reduce mortality.

Beta blockers should be used in all patients with a reduced EF to prevent symptomatic HF, even if they do not have a history of MI.
Statins

In all patients with a recent or remote history of MI or ACS, statins should be used to prevent symptomatic HF and cardiovascular events.

Control hypertension

In patients with structural cardiac abnormalities, including LV hypertrophy, in the absence of a history of MI or ACS, blood pressure should be controlled in accordance with clinical practice guidelines for hypertension to prevent symptomatic HF.
ICD Placement
To prevent sudden death, placement of an ICD is reasonable in patients with asymptomatic ischemic cardiomyopathy who are at least 40 days post-MI, have an LVEF of 30% or less, are on appropriate medical therapy and have reasonable expectation of survival with a good functional status for more than 1 year.

NO Calcium channel blockers
Nondihydropyridine calcium channel blockers with negative inotropic effects may be harmful in asymptomatic patients with low LVEF and no symptoms of HF after MI.
TREATMENT OF STAGES A TO D

Stage C
Nonpharmacological Interventions
Stage C:
Nonpharmacological Interventions

Education on self-care
Patients with HF should receive specific education to facilitate HF self-care.

Exercise training
Exercise training (or regular physical activity) is recommended as safe and effective for patients with HF who are able to participate to improve functional status.

Sodium Restriction
Sodium restriction is reasonable for patients with symptomatic HF to reduce congestive symptoms.
Stage C: Nonpharmacological Interventions

CPAP
Continuous positive airway pressure (CPAP) can be beneficial to increase LVEF and improve functional status in patients with HF and sleep apnea.

Cardiac Rehab
Cardiac rehabilitation can be useful in clinically stable patients with HF to improve functional capacity, exercise duration, HRQOL, and mortality.
Pharmacological Interventions
Pharmacological Treatment for Stage C HFrEF

Stage A and B
Class I recommendations
Measures listed as Class I recommendations for patients in stages A and B are recommended where appropriate for patients in stage C. (Levels of Evidence: A, B, and C as appropriate)
Pharmacological Treatment for Stage C HFrEF (cont.)

**Diuretics**
Diuretics are recommended in patients with HFrEF who have evidence of fluid retention, unless contraindicated, to improve symptoms.

**Ace Inhibitors/Angiotensin Receptor Blockers**
ACE inhibitors are recommended in patients with HFrEF and current or prior symptoms, unless contraindicated, to reduce morbidity and mortality.

ARBs are recommended in patients with HFrEF with current or prior symptoms who are ACE inhibitor-intolerant, unless contraindicated, to reduce morbidity and mortality.
Drugs Commonly Used for HFrEF (Stage C HF)

- **Ace Inhibitors**
  - Captopril
  - Enalapril
  - Fosinopril
  - Lisinopril
  - Perindopril
  - Quinapril
  - Ramipril

- **Angiotensin Receptor Blockers**
  - Candesartan
  - Losartan
  - Valsartan

- **Aldosterone Antagonists**
  - Spironolactone
  - Eplerenone
Drugs Commonly Used for HFrEF (Stage C HF)

- **Beta Blockers**
  - Bisoprolol
  - Carvedilol
  - Carvedilol CR
  - Metoprolol succinate XR

- **Hydralazine and isosorbide dinitrate**
Pharmacological Treatment for Stage C HFrEF (cont.)

Angiotensin Receptor Blockers

ARBs are reasonable to reduce morbidity and mortality as alternatives to ACE inhibitors as first-line therapy for patients with HFrEF, especially for patients already taking ARBs for other indications, unless contraindicated.

Addition of an ARB may be considered in persistently symptomatic patients with HFrEF who are already being treated with an ACE inhibitor and a beta blocker in whom an aldosterone antagonist is not indicated or tolerated.
Pharmacological Treatment for Stage C HFrEF (cont.)

Ace/ARB/Aldosterone Antagonist
Routine *combined* use of an ACE inhibitor, ARB, and aldosterone antagonist is potentially harmful for patients with HFrEF.

Beta Blockers
Use of 1 of the 3 beta blockers proven to reduce mortality (i.e., bisoprolol, carvedilol, and sustained-release metoprolol succinate) is recommended for all patients with current or prior symptoms of HFrEF, unless contraindicated, to reduce morbidity and mortality.
Pharmacological Treatment for Stage C HF\(r\)EF (cont.)

Aldosterone Receptor Antagonists
Aldosterone receptor antagonists [or mineralocorticoid receptor antagonists (MRA)] are recommended in patients with NYHA class II-IV and who have LVEF of 35% or less, unless contraindicated, to reduce morbidity and mortality. Careful monitoring of potassium, renal function, and diuretic dosing should be performed at initiation and closely followed thereafter to minimize risk of hyperkalemia and renal insufficiency.
Pharmacological Treatment for Stage C HFrEF (cont.)

Hydralazine/isosorbide dinitrate

The combination of hydralazine and isosorbide dinitrate is recommended to reduce morbidity and mortality for patients self-described as African Americans with NYHA class III–IV HFrEF receiving optimal therapy with ACE inhibitors and beta blockers, unless contraindicated.

A combination of hydralazine and isosorbide dinitrate can be useful to reduce morbidity or mortality in patients with current or prior symptomatic HFrEF who cannot be given an ACE inhibitor or ARB because of drug intolerance, hypotension, or renal insufficiency, unless contraindicated.
Pharmacological Treatment for Stage C HFrEF (cont.)

Digoxin

Digoxin can be beneficial in patients with HFrEF, unless contraindicated, to decrease hospitalizations for HF.

Anticoagulation

Patients with chronic HF with permanent/persistent/paroxysmal AF and an additional risk factor for cardioembolic stroke (history of hypertension, diabetes mellitus, previous stroke or transient ischemic attack, or ≥75 years of age) should receive chronic anticoagulant therapy (in the absence of contraindications to anticoagulation).
Pharmacological Treatment for Stage C HFrEF (cont.)

Nutritional supplements as treatment for HF are not recommended in patients with current or prior symptoms of HFrEF.

Hormonal therapies other than to correct deficiencies are not recommended for patients with current or prior symptoms of HFrEF.

Drugs known to adversely affect the clinical status of patients with current or prior symptoms of HFrEF are potentially harmful and should be avoided or withdrawn whenever possible (e.g., most antiarrhythmic drugs, most calcium channel blocking drugs (except amlodipine), NSAIDs, or TZDs).
Intravenous Inotropes
Long-term use of infused positive inotropic drugs is potentially harmful for patients with HFrEF, except as palliation for patients with end-stage disease who cannot be stabilized with standard medical treatment (see recommendations for stage D).

Calcium Channel Blockers
Calcium channel blocking drugs are not recommended as routine treatment for patients with HFrEF.
Pharmacological Treatment for Stage C HFpEF

Hypertension
Systolic and diastolic blood pressure should be controlled in patients with HFpEF in accordance with published clinical practice guidelines to prevent morbidity.

Diuretics
Diuretics should be used for relief of symptoms due to volume overload in patients with HFpEF.

Coronary Artery Revascularization
Coronary revascularization is reasonable in patients with CAD in whom symptoms (angina) or demonstrable myocardial ischemia is judged to be having an adverse effect on symptomatic HFpEF despite GDMT.
Pharmacological Treatment for Stage C HFpEF (cont.)

Management of Atrial Fib (AF)
Management of AF according to published clinical practice guidelines in patients with HFpEF is reasonable to improve symptomatic HF.

Pharmacologic Management
The use of beta-blocking agents, ACE inhibitors, and ARBs in patients with hypertension is reasonable to control blood pressure in patients with HFpEF.
Pharmacological Treatment for Stage C HFpEF (cont.)

Angiotensin receptor blockers
The use of ARBs might be considered to decrease hospitalizations for patients with HFpEF.

Nutritional Supplementation
Routine use of nutritional supplements is not recommended for patients with HFpEF.
TREATMENT OF STAGES A TO D

Adapted from Russell et al. Congest Heart Fail. 2008;14:316-21.
Treatment for Stage D: Advanced

Water restriction

Fluid restriction (1.5 to 2 L/d) is reasonable in stage D, especially in patients with hyponatremia, to reduce congestive symptoms.

Inotropic support

Until definitive therapy (e.g., coronary revascularization, MCS, heart transplantation) or resolution of the acute precipitating problem, patients with cardiogenic shock should receive temporary intravenous inotropic support to maintain systemic perfusion and preserve end-organ performance.

Continuous intravenous inotropic support is reasonable as “bridge therapy” in patients with stage D refractory to other treatments and device therapy who are eligible for and awaiting MCS or cardiac transplantation.
Treatment for Stage D

Inotropic Support cont’
Short-term, continuous intravenous inotropic support may be reasonable in those hospitalized patients presenting with documented severe systolic dysfunction who present with low blood pressure and significantly depressed cardiac output to maintain systemic perfusion and preserve end-organ performance.

Long-term, continuous intravenous inotropic support may be considered as palliative therapy for symptom control in select patients with stage D despite optimal GDMT and device therapy who are not eligible for either MCS or cardiac transplantation.
Inotropic Support cont’

Long-term use of either continuous or intermittent, intravenous parenteral positive inotropic agents, in the absence of specific indications or for reasons other than palliative care, is potentially harmful in the patient with HF.

Use of parenteral inotropic agents in hospitalized patients without documented severe systolic dysfunction, low blood pressure, or impaired perfusion, and evidence of significantly depressed cardiac output, with or without congestion, is potentially harmful.
Mechanical Circulatory Support

MCS use is beneficial in carefully selected* patients with stage D HFrEF in whom definitive management (e.g., cardiac transplantation) or cardiac recovery is anticipated or planned.

Nondurable MCS, including the use of percutaneous and extracorporeal ventricular assist devices (VADs), is reasonable as a “bridge to recovery” or a “bridge to decision” for carefully selected* patients with HFrEF with acute, profound hemodynamic compromise.

Durable MCS is reasonable to prolong survival for carefully selected* patients with stage D HFrEF.
Evaluation for cardiac transplantation is indicated for carefully selected patients with stage D HF despite GDMT, device, and surgical management.
